Mutagenesis Of The Mouse Genome

Mutagenesis of the Mouse Genome focuses on articles relevant to mouse chemical mutagenesis, and is dedicated to the memory of the mutagenesis pioneer, William L. Russell. Monica Justice provides an overview of the history of the Human Genome Project and use of the mouse as the primary organism for the functional annotation of the mammalian genome.

Mutagenesis of the Mouse Genome is a collection of papers originally presented at the Second Georgia Genetics Symposium in 2002 and printed in a special issue of *Genetica* in 2004. The volume opens with a wonderful, lovingly written tribute to the work of the late Dr William L. Russell and a history of mouse genetics at Oak Ridge National Laboratory, along with much information about the origins of mouse mutagenesis in relation to both human and mouse genomics.

The haploid size of the mouse genome is estimated to be 2.6 Gb; hence even at the conservative mutation rate of one every 2.7 Mb, each gamete of an ENU-treated male (G0) would carry 1,000 mutations. Of these mutations, it is estimated that 20 would potentially give rise to functional mutations since only 1–3% of the mouse genome is coding or regulatory regions.

Random mutagenesis of the mouse genome: a strategy for ...

The sequencing of mammalian genomes has shown that their gene catalogs are unexpectedly small, with ~28,000 genes. Owing to the development of mouse embryonic stem (ES) cells<sup>1, 2</sup> and a variety of mutagenic technologies<sup>3-12</sup>, it is now possible to plan a systematic assault on the mouse genome to document function. The most straightforward way to start this program is to create and characterize null alleles in the germ line.

The European dimension for the mouse genome mutagenesis ...

With the completion of sequencing of the human and mouse genomes, the interest in tools suitable for performing genome-wide mutagenesis has increased significantly. Two major mouse-mutagenesis programs have evolved: one is phenotype-driven and based on chemical (ethyl-nitroso-urea) mutagenesis ( 1 , 2 ), and the other is gene-driven and based on insertional mutagenesis ( 3 , 4 ).

If we assume a molecular weight of the diploid mouse genome of  $24 \times 10^{12}$ , then 2  $\mu$ g of genomic DNA would contain  $23 \times 10^5$  copies of diploid genome. Therefore, 2  $\mu$ g of pooled genomic DNA would include, on average, approximately six copies of genome from each individual ES cell clone, which is close to the limit of PCR detection.
